Diffusion image definition

Diffusion image definition

We define the acquired diffusion image as:

$$E : \begin{cases} \Omega_x \times \Omega_q \rightarrow \mathbb{R} \\ (\mathbf{x}, \mathbf{q}) \rightarrow E(\mathbf{x}, \mathbf{q}) \end{cases}$$

Diffusion image definition

We define the acquired diffusion image as:

$$E : \begin{cases} \Omega_x \times \Omega_q \rightarrow \mathbb{R} \\ (\mathbf{x}, \mathbf{q}) \rightarrow E(\mathbf{x}, \mathbf{q}) \end{cases}$$

The objective is to compute the diffusion PDF:

$$P : \begin{cases} \Omega_x \times \Omega_p \rightarrow \mathbb{R} \\ (\mathbf{x}, \mathbf{p}) \rightarrow P(\mathbf{x}, \mathbf{p}) \end{cases}$$

Diffusion Spectrum Imaging (DSI) - Fourier transform [Wedeen00]

q -space sampling

Pro

- 😊 Complete diffusion (angular and radial profile)
- 😊 No *a priori* on the signal

Cons

- ☹ Very long acquisition time
- ☹ High gradients lead to magnetic field distortion

Low Angular Resolution Diffusion Imaging

Diffusion Tensor Imaging (DTI) - Gaussian assumption [Basser94]

$$E(\mathbf{q}) = \exp(-\mathbf{q}^T \mathbf{D} \mathbf{q}) \quad \Rightarrow \quad P(\mathbf{p}) = \frac{1}{(|\mathbf{D}|(4\pi\tau)^3)^{1/2}} \exp\left(-\frac{\mathbf{p}^T \mathbf{D}^{-1} \mathbf{p}}{4\tau}\right)$$

q -space sampling

q -space sampling

Pro

- 😊 Reduced acquisition time
- 😊 Higher angular precision than DTI

Cons

- ☹ Simple *a priori* on the radial diffusion (Gaussian, Bessel, *etc.*)

Interest of Radial PDF

- Various brain tissues diffuse differently, which may reveal information on cells micro-structure that composed the organic tissue.
- May increase detection of anomalies such as demyelination, a symptom of multiple sclerosis.

Continuous representation of the signal

q -space sampling

Figure: A sparse sampling of the q -space.

Continuous representation of the signal

q -space sampling

Figure: A sparse sampling of the q -space.

Problem

Still insufficient number of samples for a Fourier transform. Which mathematical tool for the signal approximation ?

Continuous representation of the signal

Continuous representation of the MR signal E in the following basis (Spherical Polar Fourier SPF):

$$E(\mathbf{q}) = \sum_{n=0}^{\infty} \sum_{l=0}^{\infty} \sum_{m=-l}^l a_{nlm} R_n(\|\mathbf{q}\|) y_l^m \left(\frac{\mathbf{q}}{\|\mathbf{q}\|} \right) \quad (1)$$

where a_{nlm} expansion coefficients, R_n and y_l^m are respectively are radial and angular atoms.

The basis is *orthonormal* in spherical coordinates:

$$\int_{\mathbf{q} \in \mathbb{R}^3} \left[R_n(\|\mathbf{q}\|) y_l^m \left(\frac{\mathbf{q}}{\|\mathbf{q}\|} \right) \right] \cdot \left[R_{n'}(\|\mathbf{q}\|) y_{l'}^{m'} \left(\frac{\mathbf{q}}{\|\mathbf{q}\|} \right) \right] d\mathbf{q} = \delta_{nn'} \delta_{ll'} \delta_{mm'} \quad (2)$$

Angular Atoms

$$y_l^m = \begin{cases} \sqrt{2} \Re(Y_l^m) & \text{if } 0 < m \leq l \\ Y_l^0, & \text{if } m = 0 \\ \sqrt{2} \Im(Y_l^{|m|}) & \text{if } -l \leq m < 0 \end{cases} \quad \text{with } l \in 2\mathbb{N} \quad (3)$$

Figure: Real and symmetric spherical harmonics: first orders $l = 0, 2, 4, 6$. Blue indicates a negative value, whereas indicates red a positive value.

Linear signal estimation

The representation of the signal \mathbf{E} as a coefficient vector \mathbf{A} in the basis \mathbf{M} is expressed as:

$$\mathbf{E} = \mathbf{M} \mathbf{A}$$

The coefficient estimation is computed by the linear damped least square method:

$$\begin{aligned} \Rightarrow \mathbf{A} &= \arg \min_{\mathbf{A}} \|\mathbf{E} - \mathbf{M} \mathbf{A}\|^2 + \lambda_l \|\mathbf{L}\|^2 + \lambda_n \|\mathbf{N}\|^2 \\ &= (\mathbf{M}^T \mathbf{M} + \lambda_l \mathbf{L}^T \mathbf{L} + \lambda_n \mathbf{N}^T \mathbf{N})^{-1} \mathbf{M}^T \mathbf{E} \end{aligned}$$

where \mathbf{M} , \mathbf{E} , \mathbf{A} stands for:

$$\mathbf{M} = \begin{bmatrix} R_0(\|\mathbf{q}_1\|) y_0^0 \left(\frac{\mathbf{q}_1}{\|\mathbf{q}_1\|} \right) & \dots & R_N(\|\mathbf{q}_1\|) y_L^L \left(\frac{\mathbf{q}_1}{\|\mathbf{q}_1\|} \right) \\ \vdots & \ddots & \vdots \\ R_0(\|\mathbf{q}_{n_s}\|) y_0^0 \left(\frac{\mathbf{q}_{n_s}}{\|\mathbf{q}_{n_s}\|} \right) & \dots & R_N(\|\mathbf{q}_{n_s}\|) y_L^L \left(\frac{\mathbf{q}_{n_s}}{\|\mathbf{q}_{n_s}\|} \right) \end{bmatrix},$$
$$\mathbf{E} = (E(\mathbf{q}_1), \dots, E(\mathbf{q}_{n_s}))^T \quad \mathbf{A} = (a_{000}, \dots, a_{NLL})^T$$

Displacement PDF	\mathbb{R}^3
Diffusion signal E	\mathbb{R}^3

Table: Overview of proposed features \mathcal{G} of the PDF.

Moments

Moments of the diffusion PDF of order $a + b + c$ are expressed as the scalar product between P and H^{abc} :

$$\mathcal{G}_{abc} = \int_{\mathbf{p} \in \mathbb{R}^3} P(\mathbf{p}) H^{abc}(\mathbf{p}) d\mathbf{p} \quad \text{avec} \quad H^{abc}(\mathbf{p}) = p_x^a p_y^b p_z^c$$

These moments can be grouped as a tensor of order $a + b + c$, so that the DTI is a special case with $a + b + c = 2$.

$$\text{DTI} = \begin{pmatrix} \mathcal{G}_{200} & \mathcal{G}_{110} & \mathcal{G}_{101} \\ \mathcal{G}_{110} & \mathcal{G}_{020} & \mathcal{G}_{011} \\ \mathcal{G}_{101} & \mathcal{G}_{011} & \mathcal{G}_{002} \end{pmatrix}$$

Funk-Radon Transform (FRT)

The Funk-Radon transform approximates the ODF. It is used by HARDI methods such as the Q-Ball Imaging.

The FRT feature is written as:

$$\mathcal{G}(\mathbf{k}) = \int_{\mathbf{p} \in \mathbb{R}^3} H_{\mathbf{k}}(\mathbf{p}) P(\mathbf{p}) d\mathbf{p}$$

where $H_{\mathbf{k}}$ is the associated projection function at point $\mathbf{k} \in \mathcal{S}^2$. Let $q' \in \mathbb{R}$ be the sampling radius of the q-sphere and $\mathbf{p} = p\mathbf{r}$, so that [Tuch04]:

$$H_{\mathbf{k}}(\mathbf{p}) = 2\pi q' J_0(2\pi q' p) \delta(1 - \mathbf{r} \cdot \mathbf{k})$$

Funk-Radon Transform (FRT)

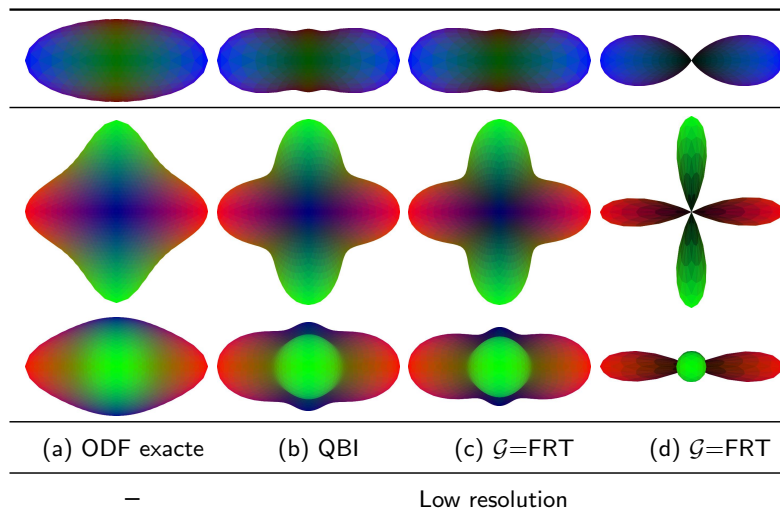

Figure: Reproduction of the QBI method by our approach.

The diffusion orientation density function (ODF) is the projection of the PDF on the unit sphere.

This feature is expressed as:

$$\mathcal{G}(\mathbf{k}) = \int_{\mathbf{p} \in \mathbb{R}^3} P(\mathbf{p}) H_{\mathbf{k}}(\mathbf{p}) d\mathbf{p}$$

where $H_{\mathbf{k}}$ is

$$H_{\mathbf{k}}(\mathbf{p}) = \delta(1 - \mathbf{r} \cdot \mathbf{k})$$

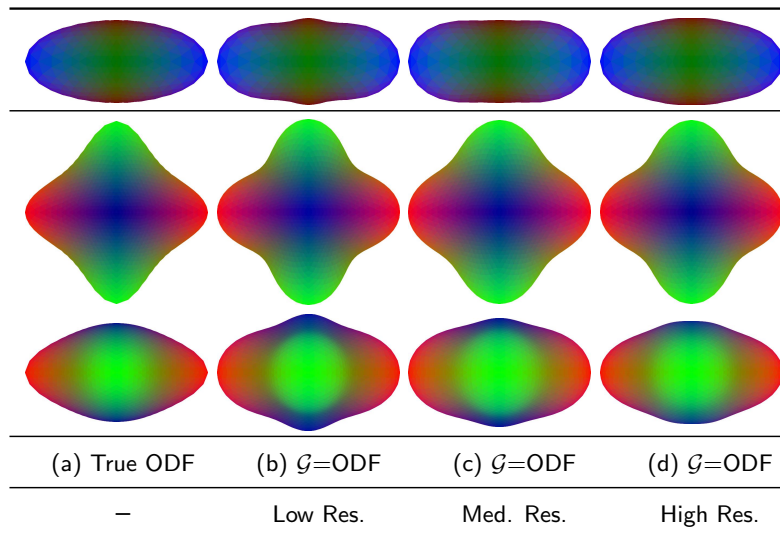

Figure: ODF approximation at low, medium and high resolution.

Our method (c) shows the obtained ODF with $b = 1000$ and 3000 s/mm^2 .

The anisotropy is a scalar measure which is useful to have hindsight on the wiring structure of the nerve fibers across the brain.

The generalized fractional anisotropy feature, which generalizes the fractional anisotropy (FA), is expressed as:

$$\text{GFA}(\mathcal{G}) = \frac{\text{std}(\mathcal{G})}{\text{rms}(\mathcal{G})} = \sqrt{\frac{\int_{\mathbf{k} \in \mathcal{S}^2} (\mathcal{G}(\mathbf{k}) - \langle \mathcal{G} \rangle)^2 d\mathbf{k}}{\int_{\mathbf{k} \in \mathcal{S}^2} \mathcal{G}(\mathbf{k})^2 d\mathbf{k}}}$$

where $\mathcal{G} : \mathcal{S}^2 \rightarrow \mathbb{R}$ is a spherical feature of the PDF (e.g. $\mathcal{G} = \text{FRT}, \text{ODF}, \text{ISO}, \text{etc.}$).

Problem

Acquisition noise not Gaussian but Rician.

Nonetheless most methods use least square estimation !

⇒ **Bias especially at low SNR values (high b values).**

Variational framework

Robustly estimate and regularize the SPF coefficients by minimizing the functional energy:

$$\min_A \left\{ \int_{\Omega_E} \left[\sum_k^{n_s} \psi(\hat{\mathbf{E}}_k) \right] + \alpha_r \varphi(\|\nabla \mathbf{A}\|) d\Omega_E \right\}, \text{ with } \hat{\mathbf{E}} = \mathbf{MA} \quad (5)$$

The best fitting coefficients A are computed with a gradient descent coming from the Euler-Lagrange derivation of the energy. This leads to a set of *multi-valued* partial derivate equation.

$$\begin{cases} \mathbf{A}_{t=0} = U_0 \\ \frac{\partial \mathbf{A}_j}{\partial t} = \sum_k^{n_s} \mathbf{M}_{k,j} \psi'(\hat{\mathbf{E}}_k) + \alpha_r \operatorname{div}(\varphi(\|\nabla \mathbf{A}\|)) \end{cases} \quad (6)$$

iteration 0

iteration 1

...

iteration n

Advantages: adaptive to noise distribution

- ψ -likelihood function adapted to MRI noise law:

The best ψ function is the one specific to MR scanners, ie. Rice distribution:

$$p(E|\hat{E}, \sigma) = \frac{E}{\sigma^2} \exp\left(\frac{-(E^2 + \hat{E}^2)}{2\sigma^2}\right) I_0\left(\frac{E \cdot \hat{E}}{\sigma^2}\right) \quad (7)$$

We seek \hat{E} which maximizes a posteriori (MAP) the log-posterior probability [Basu06]

$$\log p(\hat{E}|E) = \log p(E|\hat{E}) + \log p(\hat{E}) - \log p(E) \quad (8)$$

Consequently the pointwise likelihood is

$$\log p(E|\hat{E}, \sigma) = \log \frac{E}{\sigma^2} - \frac{(E^2 + \hat{E}^2)}{2\sigma^2} + \log I_0\left(\frac{E \cdot \hat{E}}{\sigma^2}\right) = \psi(\hat{E}) \quad (9)$$

Advantages: regularity

- Ensure a global regularity of the SPF field:

$$\varphi(\|\nabla\mathbf{A}\|) = \varphi(\sum_{nlm} \|\nabla A_{nlm}\|)$$

φ is a contour preserving function, widely used in image processing.
Example of possible regularization function φ

Simulation: validation on synthetic data (likelihood)

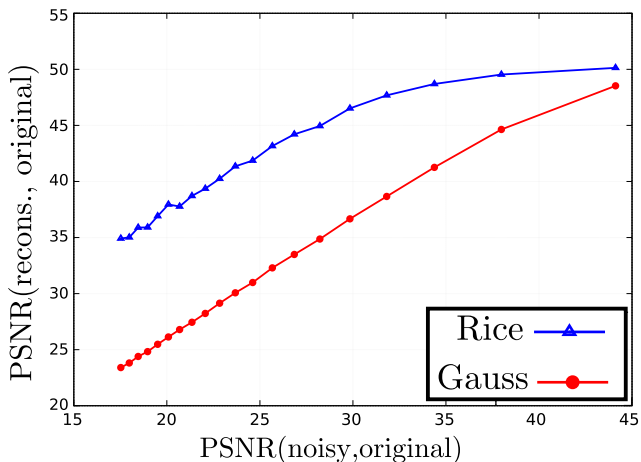

Figure: Synthetic phantom of networks of crossing fibers. Performances of likelihood functions on increasing levels of noise.

Simulation: Rician vs Gaussian likelihood function

a) Truth

b) Noisy

c) Gaussian

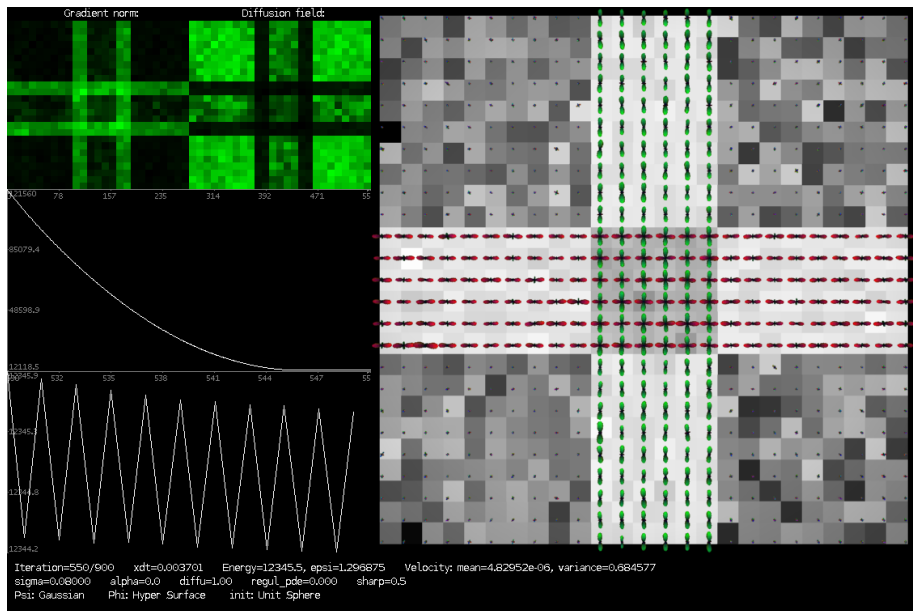

$$|Gauss - Truth|$$

d) Rician

$$|Rice - Truth|$$

Simulation: energy minimization

Results of *in-vivo* experiences

q-space Sampling Distribution

Questions

q-space Sampling Distribution

Questions

- Which sampling distribution gives the best results ?

q-space Sampling Distribution

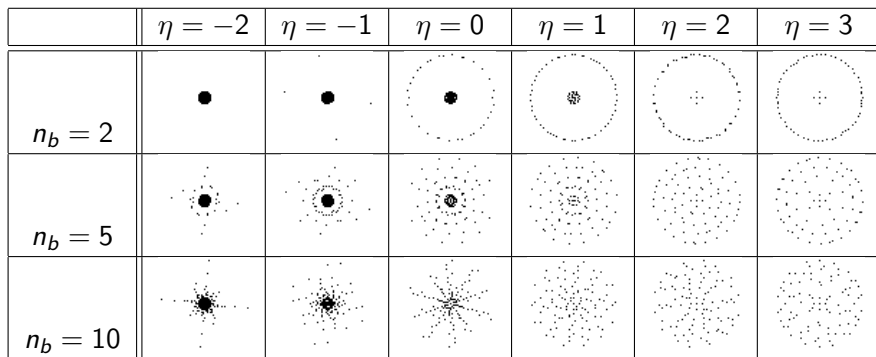

Questions

- Which sampling distribution gives the best results ?
- Is it possible to unify the sparse sampling in the literature in one model ? [Assaf05, Özarslan06, Wu07, Khachaturian07, Assemlal-et.al08, Assemlal-et.al09]

$$f_x(\eta) = \frac{q_x^\eta}{\sum_{i=1}^{n_b} q_i^\eta} n_s, \quad \text{and} \quad q_i(\beta) = \left(\frac{i-1}{n_b-1} \right)^\beta (q_{max} - q_{min}) + q_{min}$$

q-space Sampling Distribution

$$f_x(\eta) = \frac{q_x^\eta}{\sum_{i=1}^{n_b} q_i^\eta} n_s, \quad \text{and} \quad q_i(\beta) = \left(\frac{i-1}{n_b-1} \right)^\beta (q_{max} - q_{min}) + q_{min}$$

Simulation: q -space Sampling Distribution

Figure: Condition number $C = \|\mathbf{M}_{reg}\|_{\infty} \|\mathbf{M}_{reg}^{-1}\|_{\infty}$. The lower C is, the more stable the reconstruction is. Data simulates crossing fibers diffusion signal.

$L = 4, N = 3, n_b \geq 3$. (d) $\lambda_n = 10^{-4}, \lambda_l = 10^{-6}$.

(a) $n_s = 300$

No regularization.

Conclusion: 3-Robustness

Robustness to noise

Robustness to sampling distribution

	$\eta = -2$	$\eta = -1$	$\eta = 0$	$\eta = 1$	$\eta = 2$	$\eta = 3$
$n_b = 2$						
$n_b = 5$						

Thank you for your attention.

Proposition

We propose the use of Gauss-Laguerre functions:

$$R_n(\|\mathbf{q}\|) = \left[\frac{2}{\gamma^{3/2}} \frac{n!}{\Gamma(n + 3/2)} \right]^{1/2} \exp\left(-\frac{\|\mathbf{q}\|^2}{2\gamma}\right) L_n^{1/2}\left(\frac{\|\mathbf{q}\|^2}{\gamma}\right), \quad (10)$$

where γ is the scale factor.

Let L_n^k be a generalized Laguerre polynomial:

$$L_n^k = \frac{1}{n!} \sum_{i=0}^n \frac{n!}{i!} \binom{k+n}{n-i} (-x)^i \quad (11)$$

The Gauss attenuation comes from the normalization of these polynomials:

$$\int_0^\infty e^{-kx} x^k L_n^k(x) L_{n'}^k(x) dx = \frac{(n+k)!}{n!} \delta_{nn'} \quad (12)$$

Results: radial truncation order
